2006 Annual Surveys of State and Local Government Finances Methodology

The U.S. Census Bureau conducts Annual Surveys of State and Local Government Finances as authorized by Title 13, United States Code, Section 182.

This survey methodology contains information on the data collected for fiscal year 2006.

Population of Interest

The population of interest for this survey contains the 50 state governments and 89,476 local governments (counties, municipalities, townships, special districts, and school districts) including the District of Columbia. In years ending in ‘2’ and ‘7’ the entire universe is canvassed. In intervening years, a sample of the population of interest is surveyed. The survey coverage includes all state and local governments in the United States.

Content of the Survey

For both the census and annual survey, the finance detail data are equivalent, encompassing the entire range of government financial activities - revenue, expenditure, debt, and financial assets. Revenue data include taxes, charges, interest, intergovernmental revenues, and other earnings. Expenditure data include total by function (such as education and police protection) and by character (such as current operations and capital outlays). Debt data include issuance, retirement, and amounts outstanding. Financial assets data include securities and other holdings, by purpose.

The forms listed below are used to collect the data. The variables collected on these forms are explained in detail in the 2006 Government Finance and Employment Classification Manual. With the exception of the F13 and F25 questionnaires, respondents may reply to these regular ‘F’ forms questionnaires over the Internet.

Sample Design

Description of design:

The 2006 sample for the Annual Surveys of State and Local Government Finances was selected from the 2002 Census of Governments. It was designed to produce state by level of government estimates with a coefficient of variation of 3 percent or less for long-term debt, total revenue, and total expenditure. The sample will produce state and local government estimates with a coefficient of variation of 5 percent or less on the following 11 major finance items: long-term debt, total revenue, total expenditure, criminal justice, education, highways, health/hospitals, housing, capital outlay, utilities, and welfare. The sample included all independent schools since their data were obtained from other education surveys. All other government units were selected into the sample with a probability proportional to their size, either total expenditure or long-term debt. All state governments were included in the sample. The sample was adjusted as follows:

- Births of general purpose governments and independent schools since the completion of the 2005 ASGF processing cycle and identified by GOVS were all added to the sample and assigned a weight of 1.0000.
- Births of special district governments that met initial certainty were also included with a weight of 1.0000. All other special district government births were sampled at a rate of 1 in 25.
- Deaths (dis-incorporated units) since the completion of the 2004 Annual Surveys of State and Local Government Finances processing cycle were removed from the sample.

The initial certainty criteria for the 2006 sample were as follows:

- All county governments with a 2002 population of 100,000 or more.
- All cities with a 2002 population of 75,000 or more.
- All townships in New England and Middle Atlantic states with a population of 50,000 or more.
- All special districts meeting any of the following three conditions:
  1. Full-time equivalent employment of 1,000 or more;
  2. A function code of 42(Mortgage Credit), 92(Electric Power), 93(Gas
Supply), or 94 (Transit);

3. Either $20+ million total revenue or expenditure.
   - Special districts that are the only special district for a state and specific function code.

Sample Frame:

The sampling frame for the 2006 Annual Surveys of State and Local Government Finances was the 2002 Census of Local Governments file, updated by births, deaths, and mergers that took place since 2002. Altogether, there were 79,360 local governments of Type 1, 2, 3, or 4. All state governments and school districts were included in the sample frame.

Weighting:

The weight for each unit in the sample is the inverse of that unit’s probability of being selected into the sample. For example, for units that were included in the sample with a probability of .02, the weight is (1/.02)=50.0000. For units that were included in the sample with a probability of 1.0000, the weight is 1.0000.

Sample size:

The sample size was around 12,000 non-school units. Of the total number of governments in the non-school sample, 15.0% were counties, 26.0% were cities, 19.0% were townships, and 40.0% were special districts. All 50 state governments and the District of Columbia were certainty units with a weight of 1.0000.

Note, that the entire sample included all independent schools since their data were obtained from other education surveys. Of the total number of governments in the entire sample, approximately 7.0% were counties, 11.0% were cities, 8.0% were townships, 18.0% were special districts, and 56.0% were school districts.

Data Collection

Data collected for the 2006 Annual Surveys of State and Local Government Finances are public record and are not confidential, as authorized by Title 13, United States Code, Section 9. Data for this survey were collected using the forms listed in the Content of the Survey section and through state government administrative records.
The data collection for the state and local finance survey is made up of three modes to obtain data: mail canvass, Internet collection, and central collection from state sources. Collection methods vary by state and type of government.

Reviews of government accounting records provide data for most state government agencies and the 48 largest and most complex county and municipal governments. Data for local governments in about 26 states are consolidated and submitted by state agencies (central collections), usually as electronic transmissions or mutually developed questionnaires. Each of these central collection arrangements is unique, conforming to the Census Bureau's and the states' requirements.

Data for the balance of local governments were obtained via mail questionnaires sent directly to county, municipal, township, and special district governments.

In some cases the data from central collections and mail canvass procedures were incomplete or questionable. If Census Bureau analysts were unable to obtain corrected data from original sources, they attempted to obtain data from Comprehensive Annual Financial Reports (CAFRs). In many instances, supplied/compiled data are supplemented with secondary sources, such as debt information from Mergents.

**Note:** All governments that received a mail questionnaire had the option of submitting their response via the Internet.

The following are important dates in the data collection process for fiscal year 2006:

### Data Processing

**Editing:**

Editing is a process that tries to ensure the accuracy, completeness, and consistency of the survey data. Efforts are made at all phases of collection, processing, and tabulation to minimize reporting, keying, and processing errors.

Although some edits are built into the Internet data collection instrument and the data entry programs, the majority of the edits are performed post collection. Edits consist primarily of four types: (1) **consistency edits**, (2) **historical ratio edits** of the current year's reported value to the prior year's value, (3) **current year ratio edits**, and (4) **balance checks**.
The **consistency edits** check the logical relationships of data items reported on the form. For example, if interest on debt is reported, then there must be debt.

The **historical ratio edits** compare data for the current year to data for the prior year or prior census year. If data fall outside of acceptable tolerance levels, the item is flagged for further review. For example, the reported property tax for the current year may be compared against the property tax last year, if the reporting unit was in last year’s sample. If it was not in last year’s sample, the current year value is compared to the prior census year value.

The **current year ratio edits** compare one data item on the form against a different data item. If data fall outside of acceptable tolerance levels, the item is flagged for further review. For example, airport expenditure to airport revenue is a current year ratio.

Balance checks are checks of linear relationships that exist in the data. Debt flow is an example of a **balance check**. The ending debt must equal the beginning debt plus the debt issued minus the debt retired.

After all data are edited and imputed, they are aggregated. A macro-edit, or aggregate-level, review is conducted with current year state aggregates compared to prior year and prior census aggregates. Macro-level ratio edits and tolerance levels were developed using the current year data.

For the **ratio edits**, **consistency edits**, **balance checks**, and **macro edits**, the edit results are reviewed by analysts and adjusted as needed. When the analyst is unable to resolve or accept the edit failure, contact is made with the respondent to verify or correct the reported data. The results of the action are tracked with a data edit flag.

**Imputation:**

Not all respondents answer every item on the questionnaire. There are also questionnaires that are not returned despite efforts to gain a response. Imputation is the process of filling in missing or invalid data with reasonable values in order to have a complete data set for analytical purposes. For census years, the complete data set is also needed for sample design purposes.

For nonresponding general purpose governments, imputations for missing units are based on recently reported historical data from either a prior year annual survey or the most recent census, adjusted by a growth rate. If no historical data are available, data from a randomly selected similar unit are adjusted by the ratio of the populations of the nonresponding and randomly selected donor governments.

The imputations for nonresponding special districts are done similarly. If prior year reported data are available, the prior year data for the nonrespondent are adjusted by a growth rate that is determined from reporting units that are similar to the nonrespondent. Special districts are similar if they are of the same function code and similar geography,
e.g., police protection in a state or water transport in a region. For nonresponding special districts with no recently reported data available, data are used from a randomly selected donor that is similar to the nonrespondent. In cases where good secondary data sources exist, the data from those sources are used.

For individual questionnaire items that are not reported by general-purpose governments or dependent and independent school districts, either data from another source, pro-rating of totals, or prior year data are used to give a complete dataset.

**Note:** Between years 2002 through 2006, individual government imputed data were not released to the public.

**Estimation:**

After the data were edited and imputed, the estimates were calculated using a regression estimator for most variables. For capital outlay and debt variables, a Horvitz-Thompson estimator was used. Downloadable files of the final estimates are available on the website.

**Variance:**

Data that are derived from the annual sample survey are subject to sampling error. The statistics in this report that are based wholly or partly on data from the sample are apt to differ from the results of a census covering all governments. Estimates based on a sample survey are subject to sampling variability. The particular sample used is one of a large number of all possible samples of the same size that could have been selected using the same sample design. Each of the possible samples would yield somewhat different results.

The standard error is a measure of the variation among the estimates from all possible samples and thus is a measure of the precision with which an estimate from a particular sample approximates the average results of all possible samples. Each viewable table contains a column that gives users the coefficients of variation (or relative standard error) that have been computed for these estimates. The coefficient of variation is the estimated standard error expressed as a percent of the estimated total or proportion.

State government financial statistics result from a complete canvass of all state government agencies. Consequently, there is no associated measure of sampling error, such as the coefficient of variation. However, these statistics are subject to non-sampling error. Such error includes inaccuracies in classification, coverage, and processing.

Although efforts were made at all phases of collection, processing, and tabulation to minimize errors, the data were still subject to errors from imputing for missing data, errors from miscoding, and errors in coverage. Every effort was made to keep such
errors to a minimum through examining, editing, and tabulating the data.

The CVs (coefficient of variation) presented in tables can be used to derive the standard error of the estimate. The standard error can then be used to derive interval estimates with prescribed levels of confidence that the interval includes the average results of all samples:

a. intervals defined by one standard error above and below the sample estimate will contain the true value about 68 percent of the time;

b. intervals defined by 1.6 standard errors above and below the sample estimate will contain the true value about 90 percent of the time;

c. intervals defined by two standard errors above and below the sample estimate will contain the true value about 95 percent of the time.

The user can calculate the standard error by multiplying the CV presented in the tables by the corresponding estimate. The CVs presented in the tables are in percentage form and must be divided by 100 before being multiplied by the estimate. This standard error estimate can then be used to get a 90 percent interval estimate by multiplying it by 1.6 and adding the result to the estimated total to get the upper bound and subtracting it from the estimated total to get the lower bound.

Data Quality

Data quality/nonsampling errors (including response rates):

Although every effort (as described in the Data Processing section) is made in all phases of collection, processing, and tabulation to minimize errors, the sample data are subject to nonsampling errors such as inability to obtain data for every variable from all units in the sample, inaccuracies in classification, response errors, misinterpretation of questions, mistakes in keying and coding, and coverage errors. These same errors may be evident in Census collections and may affect the Census of Governments data used to adjust the sample during the estimation phase and used in the imputation process.

The overall response rate to the 2006 Annual Surveys of State and Local Government Finances was 88.4%. Data for the 50 state governments were compiled from records supplied by each state government. The response rate was calculated as the number of responses received divided by the number of governments in sample.
