INCOME OF FARM-OPERATOR FAMILIES IN 1949

Ernest W. Grove, Division of Statistical and Historical Research, Bureau of Agricultural Economics

INTRODUCTION

The 1950 Census of Population obtained information on the money income of individuals and families in 1949 on the basis of a 20-percent sample. The tabulations of these data as published in regular reports of the Census of Population show separate income distributions for families and unrelated individuals in the urban, rural-nonfarm, and rural-farm populations. But farm operators and their families, defined in terms of the definition of a farm established for the 1950 Census of Agriculture, could not in many cases be identified as such from information available from the Population Census alone. This identification could be made and an income distribution established for all farm-operator families only by combining information obtained in the Agriculture and Population Censuses.

In the Population Census, information was requested of persons 14 years of age and over in the sample on the following income categories: (1) The amount of money wages or salary received in 1949; (2) the amount of net money income received from self-employment in 1949 (farm, business, or professional practice); and (3) the amount of other income received in 1949, such as interest, dividends, veterans' allowances, pensions, or rents. If the person was the head of a family, these three questions were repeated for the other family members as a group to obtain the income of the whole family.

By identifying heads of families in the 20-percent sample of the Population Census who were operators of farms included in the Census of Agriculture, and by combining information from the two Censuses, family-income data from the Population Census were tabulated for farm-operator families in relation to the economic classification of farms determined from the Agriculture Census.

LIMITATIONS OF THE DATA

The figures on income, as indicated in regular reports of the Census of Population, are subject to errors of response and nonreporting which probably lead to some understatement of total income. The schedule entries are generally based not on records but on memory. The memory factor in data derived from field surveys of income probably produces underestimates because the tendency is to forget minor or irregular sources of income. Other errors of reporting are due to misunderstanding of the income questions or to misrepresentation.

Another possible source of understatement is the assumption made in the editing process that there was no other income in the family when only the income of the head of the family was reported. This assumption was adopted for about 5 percent of the families in order to make maximum use of the information obtained. In most of the fully reported cases, the head's income constituted all or most of the total family income.

These qualifications apply to all the income data collected in the 1950 Census of Population, including those here presented for farm-operator families. There are three additional known limitations in the data for farm-operator families. First, there is evidence of some nonreporting of farm income, total family income having been recorded in a significant number of cases exclusive of income received from the farm operated. The evidence is given in table 3, and rough adjustments have been made in tables 4 and 5 to allow for such nonreporting. However, no adjustments were feasible in the straight family income distributions of tables 1 and 2.

The second limitation arose in the process of matching agriculture reports with their counterparts among the population reports. In a few cases the operator of a farm determined from the Agriculture Census, whose name appeared on a sample line of the Population Census, turned out not to be the family head. Total family income in such cases was not available, but the personal income of operators who were not family heads was counted as total family income in the income tabulations. In some of these cases,

the operator's income may have been the same as or a close approximation of total family income, but in other cases it most probably was not.

Separate analysis of this group shows a distribution of income considerably different from that of family heads and an estimated average reported income about 20 percent lower than the average income of families with operator heads. However, the number involved is so small—only 3 percent of the total—that their inclusion is not believed to have had any significant effect on the results. For example, the estimated average of all family incomes would not have been increased by more than one percent if operators who were not family heads had been excluded.

The third limitation, also a minor one, arose from the fact that a small segment of the agriculture reports could not be matched with corresponding population reports. The expanded agriculture sample covered 5,300,000 farms, the population sample only 5,341,000. The difference of 39,000 is primarily farms where the operator's residence was not in the same enumeration district as his farm and the matching population report could not be located. In non-resident cases for which the schedules were matched—that is, where the operator and his family lived in the same enumeration district though not on the farm itself—family incomes averaged from 20 to 25 percent higher than the incomes of farm-resident operator families. There is a strong probability, therefore, that family incomes for the unmatched cases were on the whole quite a bit higher than the general run of farm-operator family incomes. Again, however, the number involved is too small—less than one percent of the total—to have any significant effect on the over-all results.

SUMMARY DISTRIBUTIONS OF FAMILY INCOME

Subject, therefore, to the general qualification that the degree of understatement of income may be slightly greater for farm-operator families than for other families, the distribution of all farm-operator families in the United States by total money income is given in table 1 and compared with national distributions for the rural-farm and total populations taken from regular reports of the Census of Population. The latter also show income distributions of persons 14 years of age and over by major occupation group, including farmers and farm managers as one group. These represent persons whose principal occupation in the week preceding the census was farmer or farm manager, a less inclusive definition than that of farm operator in the Census of Agriculture. These income distributions, moreover, reflect the personal income of those farm operators included therein, not the total income of their families, and thus cannot be compared with the distribution of farm-operator families by total family income given in the first column of table 1.

An income distribution of families whose heads reported the major occupation of farmer or farm manager would be of some

FARMS AND FARM PEOPLE

comparative interest, but such a distribution has not been tabulated from the 1950 Census data. Consequently, of the 1949 income distributions available from published Census reports, that for rural-farm families, given in the second column of table 1, seems to be most nearly comparable with the distribution for farm-operator families developed in this study. Most farm-operator families are rural-farm families. However, a few live on urban farms and a few others do not live on the farms they operate or on any other farm. On the other hand, rural-farm families would include some farm-laborer and other families who live on rural farms but do not operate them.

Despite these differences, farm-operator families and rural-farm families overlap to a considerable extent. As might be expected, therefore, the income distributions of the two groups are quite similar. Also as expected, because rural-farm families include some farm-laborer families, the median income of farm-operator families in 1949 was a little larger than that for rural-farm families—\$1,867 as compared with \$1,729.

The median income of operator families was only 61 percent as large as that for all families in the United States. This comparison reflects money income only, and nonmoney income is relatively much more important for farm-operator families than for others. But while the inclusion of nonmoney income would certainly have reduced the difference just cited, it would probably not have eliminated it.

It should be noted that about 4 percent of all farm-operator families as shown by this report for the United States are single-person families—"unrelated individuals" in the usual terminology of income distributions. There is, therefore, some question as to whether income distributions for operator families should be compared with other distributions for families alone or for families plus unrelated individuals. However, the 4 percent of unrelated individuals included in the operator distribution compares with 11 percent for the total of rural-farm families and unrelated individuals and 22 percent for all families and unrelated individuals in the United States. In view of these wide differences in the relative importance of unrelated individuals, and considering the fact that their incomes are generally much lower than those of families, the more reasonable comparison would seem to be with income distributions for families alone.

The highest regional median income for farm-operator families in 1949 was \$2,682 in the Western region (see table 2). At \$2,438 in the North, it was not much lower. But the median income for operator families in the South was only \$1,284, about half that of the other two regions. The same regional order, and about the same relative differences, are evident in the median incomes for all families in the three regions—and also in the ratios of operator-family to all family incomes. The median income of operator families was 78 percent as large as the median for all families in the West, 73 percent in the North and 57 percent in the South. The income distribution for operator families in the South includes cropper families.

ANALYSIS OF FAMILY INCOME BY ECONOMIC CLASS OF FARM

Tables 3-5 summarize the results of an analysis, for the United States as a whole, of the data on farm-operator family incomes in 1949 by economic class of farm. The various economic classes of farms as established in the 1950 Census of Agriculture are fully defined in terms of upper and lower limits for value of farm products sold (see table 4), except for class VI and part-time farms which are distinguished on the basis of criteria set forth in footnote 6 of table 4. This is the first time that detailed income data have been obtained for farm-operator families associated specifically with each economic class of farms.

Class I and class II farms are shown separately in tables 3-5 in order to bring out the marked differences in their income characteristics. They are lumped together in other tabulations in this report because for most other characteristics they are not significantly different and also because the size of the sample on a regional basis did not in some cases permit separate tabulations for class I farms.

"Abnormal" farms, lumped with part-time farms elsewhere in this report, are excluded entirely from tables 3-5. They include such categories as public and private institutional farms, community enterprises, experiment station farms, and grazing associations. Information was obtained in some cases on the wages or

salaries received by hired managers, but, in general, family-income data are not applicable to farms of this type.

Table 3 shows the total number of farms in each economic class, the number for which total family income was recorded in the Population Census, and the percentages reporting each of the six sources of family income. Total family income was recorded for 90 percent of all farms, and this ratio did not vary materially among the different economic classes. On the other hand, there were significant variations in the percentages reporting each of the specified sources of income.

A third of all farm operators reported income from wages or salaries. However, only a fifth of the commercial operators reported such income whereas three-fifths of the noncommercial operators reported it. Within the commercial group, the percentage of operators reporting wages or salaries increased uniformly from class I to class VI with two exceptions: (1) The percentage for class I operators was greater than that for either class II or class III operators; and (2) the percentage for class VI operators was smaller than that for class V operators. By definition, a class VI operator did not work more than 99 days off his farm in 1949. In view of this limitation, it is worth noting that a fourth of all class VI operators reported some wage or salary income in 1949, a higher fraction than that for

INCOME OF FARM-OPERATOR FAMILIES

²And in a few cases from another farm.

³Excluding "abnormal" farms to which family income data are not generally applicable.

any other commercial class except V. As to class I operators, the percentage reporting wage or salary income was undoubtedly boosted by the relatively greater incidence of hired managers as operators in this class. If managers had been excluded, class I operators would probably have shown the smallest percentage of any class.

Wage or salary income of family members other than the farm operator was reported by nearly a fifth of all farm-operator families, but by only a sixth of all commercial farm families as compared with a fourth of the noncommercial group. As with operators' wage or salary income, the incidence of wage or salary income of other family members increased uniformly from class I to class V within the commercial group, and then dropped off in class VI. On the other hand, the percentages reporting self-employment income of other family members declined somewhat from class I to class VI. In general, self-employment income of other family members was reported rather infrequently, but unlike the other supplementary sources of farm-operator family income it was reported a little more frequently by the commercial than by the noncommercial or "other farm" group.

Income other than earnings from wages, salaries, or self-employment was reported by a fifth of the commercial farm operators, by nearly a third of the noncommercial operators, and by a fourth of the total for the two combined. Relatively fewer class VI operators reported income from these other sources than did the operators of any other class, evidently a reflection of the definitional limitation imposed on class VI with respect to family income from nonfarm sources. Income other than earnings received by other family members was reported for relatively few families, but the incidence of this type of income was nearly twice as great for noncommercial farm families as for commercial.

The column of percentages in table 3 referring to income of the operator from his farm needs to be interpreted with some care for two reasons. First, the percentages reflect reports of the operator's income from any nonfarm business or professional practice he may have had as well as from his farm. This double coverage is probably negligible for commercial operators, but it may be of some importance in the noncommercial group. The second difficulty is that, despite the possibility of double coverage just mentioned, the percentages are low from the standpoint of farm income alone.

In the income tabulations of this study, it was not possible to distinguish between a report of "zero" or "none" and a report of "information not available." This necessitated the general assumption, in analyzing the data, that only those reporting income from a particular source had any income from that source. The result may be some understatement of family income. But there is no definite evidence of understatement except in the case of income of the operator from his farm. And

in that case some allowance for nonreporting, however arbitrary, seemed essential.

It would not be unreasonable to expect 100 percent or at least nearly 100 percent frequencies in the column for farm income of the operator. Instead, family income was recorded exclusive of any income from the farm—and from any nonfarm business or professional practice—for 11 percent of the commercial farms and for 57 percent of the noncommercial farms. Within the commercial group, the nonreporting of farm income was greatest in classes V and VI. It was also greater in class I than in classes II, III, and IV.

There is no single factor to account for this situation. Probably the principal elements that contribute to a full explanation are the following:

(1) **New farm operators in 1950** when the census was taken—persons who were not farm operators in 1949 and consequently had no self-employment income in 1949. However, the number of such new operators was probably quite small in relation to the total number of operators, and this small number must have been fairly well distributed among all the economic classes. Consequently, such new operators can account for only a small fraction, probably less than one percent, of the total nonreporting of farm income—and for none of its variation among economic classes.

(2) **Hired managers as farm operators** who reported their income from wages or salaries—but not any farm income because that accrued to absentee owners. The 1950 Census of Agriculture found 23,000 hired managers in all, or less than a half of one percent of all farm operators. Clearly, this has very little general significance. But it probably does account for the relatively high incidence of nonreporting for class I farms, where nearly 7 percent of the operators are hired managers. If hired managers had been eliminated, the percentage of class I operators reporting their farm income would probably have been the highest of any class, though still somewhat short of the necessary 100 percent. However, the incidence of nonreporting would then have increased almost continuously from class I to class VI, and on to part-time and residential farms—making the third and fourth explanatory factors discussed below more plausible than they might otherwise be.

(3) **Misrecording of farm income under another heading.**—This undoubtedly occurred in some instances when, through error on the part of either the enumerator or the respondent, the operator's income from his farm was erroneously counted as income from wages and salaries, income from other sources, or as income of other family members. The frequency of this type of misrecording is unknown, but it was probably quite small. To the extent that it occurred, however, it may have been more common in the lower value-of-sales classes than in the higher.

(4) **Farm income not reported because it was negligible** after expenses, or even a net loss on a cash basis. A report was

supposed to be made in any case, and some operators did report zero or negative net incomes. But it seems likely that others simply failed to mention their farm income when it was negligible or negative in amount. This could occur at any level of value of products sold, but the lower the latter the more likely it would be. This type of nonreporting, therefore, was probably most prevalent among part-time and residential farm operators, and to a lesser extent perhaps also among classes V and VI commercial operators.

(5) Farm income simply not reported.—The four factors mentioned above account for some of the nonreporting in all economic classes, and probably most of it in the lower value-of-sales classes. But some remains unaccounted for. Critical examination of a small group of the individually matched reports strongly suggests that significant amounts of farm income were simply not reported in a few cases, but that family income was recorded anyway. This was probably most common in the case of class I-III operators and perhaps class IV also.

Table 4 shows averages by economic class of farm for the value of farm products sold, for the total of eight expense items reported on the agriculture questionnaire, and for the first minus the second. Using these independently reported data as a partial guide, together with the conclusions described above with respect to the interpretation of nonreporting, averages were also computed by economic class of farm for (1) the net income of operators from their farms (including any income from nonfarm business or professional practice), and (2) total farm-operator family income, allowing in both cases for nonreporting in the first. In their general effect, these averages are based on the assumption

that unreported farm income had an average of zero for class V, class VI, part-time, and residential farms, but that its average was equal to that of reported farm income for farms in classes I-IV. In other words, the distributions of family income were accepted as reported for the first group, but were in some small degree adjusted upward for the second. Medians of family incomes actually reported are given in table 4, by economic class of farm, for comparison with the adjusted arithmetic means of family income.

The adjusted averages of family income are based on totals of family income in each economic class which were obtained as the sum of (1) income aggregates derived from size distributions for each of the three sources of operators' income and (2) actual totals of income reported for each of the three sources of income of other family members. However, the totals of family income obtained in this manner were also checked with and in some cases adjusted to independent totals developed from the size distributions of family income itself. Assumptions made in deriving aggregates from size distributions were (1) that averages for income intervals up to \$5,000 were equal to their respective mid-points, (2) that averages for intervals above \$5,000 were a little lower than the mid-points, (3) that farm losses for operators reporting them averaged \$750, and (4) that averages for the open-end interval of \$10,000 and over were \$14,000 in the case of wages and salaries and \$15,000 in all other cases with one exception, namely (5) that the average farm income of class I operators in the open-end interval was \$25,000. This last assumption is quite arbitrary, but it is consistent with the known characteristics of class I farms.

Table 4.—AVERAGE VALUE OF FARM PRODUCTS SOLD, AVERAGE TOTAL OF SPECIFIED EXPENDITURES, AND AVERAGE FARM AND FAMILY INCOME IN 1949 FOR FARM-OPERATOR FAMILIES, BY ECONOMIC CLASS OF FARM, FOR THE UNITED STATES

Economic class of farm	Value of farm products sold			Average per farm of specified expenditures ¹	Calculated net value of farm products sold per farm ²	Average income of farm operator from farm ³	Adjusted average family income ⁴	Median family income

¹Average expenditure per farm for hired labor; machine hire; feed for livestock and poultry; purchase of livestock and poultry; seeds, bulbs, plants, and trees; gasoline and oil; tractor repairs; and other machinery repairs. These items account for approximately 65 percent of the total production expenses of farm operators in 1949 according to estimates by the Bureau of Agricultural Economics of the United States Department of Agriculture.

²Average value of farm products sold minus total of specified expenditures.

³And from nonfarm business or professional practice, if any, applying mainly to operators of part-time and residential farms.

⁴Adjusted for nonreporting of operator's income from farm.

⁵Excluding "abnormal" farms to which family income data are not generally applicable.

⁶With the same limits for value of farm products sold, class VI and part-time farms are distinguished by the fact that the latter include all farms in this value-of-sales group where (1) the operator worked 100 or more days off the farm in 1949 or (2) nonfarm family income was larger than the value of farm products sold.

INTERPRETATION OF THE RESULTS

Money incomes of all farm-operator families in the United States averaged \$2,650 in 1949. Family incomes in the case of commercial farms averaged \$2,815, or a fourth higher than the average of \$2,260 for noncommercial farms. There was wide variation in family incomes among the various classes of commercial farms, ranging from an average of more than \$10,000 for class I farms down to only \$975 on the average for class VI farms. Incomes of part-time farm families averaged \$2,400, 10 percent above the average for residential farm families and almost as large as the average family income on class IV commercial farms.

Median family income was, of course, consistently lower than the arithmetic mean for the same economic class, and tended to be a smaller fraction of the arithmetic mean at the higher levels. The medians, however, show relationships among the economic classes very similar to those indicated by the arithmetic means.

The net money income of operators from their farms, including also any other self-employment income they may have had, averaged \$1,575 for all farm operators in 1949. The average for commercial operators was \$2,075; that for noncommercial operators was only \$385, probably including at least some nonfarm business and professional income. Among the various classes of commercial operators, average self-employment income varied from \$8,880 for class I operators down to \$550 for class VI operators. For part-time farmers, average self-employment income was \$440, a fourth higher than the average for residential farmers but below that for even the lowest commercial class.

Because the Bureau of Agricultural Economics regularly publishes annual estimates of the average income of all farm operators without any breakdown between commercial and noncommercial operators, considerable interest attaches to the question as to how the average farm income of commercial operators compares with that for all operators taken together. Although blurred by the inclusion of some nonfarm business and professional income,

the data in table 4 nevertheless throw considerable light on this question. The average of \$2,075 for commercial operators is 32 percent larger than the average for all operators. If the income from nonfarm businesses and professional practices—included mostly for noncommercial operators—could be eliminated altogether, the commercial average would most probably be from 35 to 38 percent higher than the over-all average. On the other hand, it must be remembered that this refers to money income alone, whereas nonmoney income from the farm is more evenly distributed than money income. Nonmoney income is relatively much more important for noncommercial than for commercial farms; and if it were to be included the differential would be reduced again, probably to around 26 or 27 percent.

This estimate for 1949 may be compared with an estimated differential of 27 percent in 1944, based largely on a study of data obtained in the 1945 Census of Agriculture. (See *Sizes of Farms in the United States* by Kenneth L. Bachman and Ronald W. Jones, U. S. Department of Agriculture, Technical Bulletin No. 1019, July 1950, page 7.) Evidently the average income relationship between commercial farms and all farms did not change very much from 1944 to 1949, nor has this relationship been disturbed by the simplification of definitions for commercial and noncommercial farms in the 1950 Census.

The average of operators' net money income for all farms in table 4 is from 10 to 15 percent lower than a similar average for 1949 derived from aggregate estimates of farm cash income and expenses published by the Bureau of Agricultural Economics. If nonfarm business and professional income were removed from the former average, the difference would probably be around 15 percent. Before adjustment for nonreporting of farm income, the discrepancy was probably close to 20 percent.

The independent data on farm expenses and value of products sold, taken from the 1950 Agriculture Census, provide some basis for checking the class averages of operators' net money income from the farm in table 4. However, the data on expenses do not cover all expenses, and the proportion that they do cover may vary somewhat among the different economic classes. In addition, there is probably some understatement in the value of products sold, and this also may vary in relative importance by economic class.

For these reasons, the information obtained in the Agriculture Census cannot provide any conclusive test of the reliability of the income data obtained in the Population Census. In fact, an examination of the data in table 4 indicates that only for class VI farms are the averages derived from the Agriculture and Population Censuses clearly inconsistent, although there is also some evidence of inconsistency in the case of part-time and residential farms.

By definition, operators of class VI farms cannot have had any significant amounts of nonfarm business or professional income; and the average self-employment income of \$550 for class VI operators—based on the assumption that unreported farm income was zero—must have been almost entirely farm income. That being the case, it cannot be reconciled with an average value of only \$690 for farm products sold as reported in the Agriculture Census, along with an average total of \$350 for the eight reported expense items.

There are three possible explanations for this inconsistency, namely, that class VI operators (1) exaggerated their net income in the Population Census, (2) overstated their expenses in the Agriculture Census, or (3) understated the value of farm products sold as reported in the Agriculture Census. The first two of these cannot be completely ruled out, but only the last seems particularly plausible. If it is accepted as the principal explanation, the value of farm products actually sold by class VI operators must have averaged from 25 to 50 percent higher than was reported. But regardless of the reason or reasons for the inconsistency, the fact remains that these class VI operators were really low-income farmers with an average net family income of less than a thousand dollars in 1949.

The first explanation for the inconsistency listed above, namely, exaggeration of net money income as reported in the Population Census, does not seem very likely in view of the repeated occurrence of general under-reporting in various field surveys of income. On the other hand, it cannot be altogether dismissed as an impossibility. The Population Census obtained information on the operator's farm income in response to a single question: "Last year, how much money did he earn working in his own business, professional practice, or farm? (Enter net income)." In answering this question, class VI operators may have overlooked some of their legitimate expenses, such as depreciation, which a more detailed questionnaire, covering both gross income and expenses, would have revealed. Such a detailed questionnaire was used in the last previous field survey of farm operators' income, covering the year 1946, and the results indicated a much greater concentration of cases in the lower net income and net loss brackets than is to be found in the 1949 distributions here presented. (See *The Size Distribution of Farm Operators' Income in 1946* by Nathan M. Koffsky and Jeanne E. Lear, U. S. Department of Agriculture, Bureau of Agricultural Economics, Washington, D. C., September 1950.) On the other hand, it must also be noted that the unadjusted results of the detailed 1946 questionnaire uncovered only half of the total net money income actually received by farm operators from farming in that year as contrasted with a coverage of at least 80 percent in the unadjusted data for 1949. In the absence of any conclusive evidence one way or the other, understatement of the value of farm products sold remains by far the more plausible explanation of the discrepancy found in the data for class VI operators.

There is a possibility that the value of farm products sold was considerably understated by part-time and residential farm operators as well, although the evidence is weaker for those two classes of operators than for class VI operators. Data from the Agriculture Census on expenses and products sold suggest that net money income from the farm was very small on the average for part-time farmers, and a substantial average net loss for residential farmers. Since residential farmers outnumber part-time farmers, an average for the two combined could not exceed zero and would probably be negative. But this implies that, on the average, all of the self-employment income reported by these farmers in the Population Census was from nonfarm businesses and professional practices. It is rather difficult to believe that enough part-time and residential operators has this type of nonfarm income for the over-all averages of their self-employment incomes to be as high as they are without some positive farm income being included as well. And if any farm income is included at all, the value of farm products sold must on the whole have been understated.

Additional indirect evidence on this question is furnished by the data on major occupation reported by farm operators in the Population Census. "Farmer or farm manager" was the occupation reported by 43 percent of all operators classified as part-time or residential on the agriculture questionnaire. This percentage is the same as the percentage of part-time and residential operators who reported self-employment income (table 3). The identity of these two percentages is purely coincidental, of course, for the occupational data refer to principal occupation in the week preceding the census in 1950, whereas the income data refer to the year 1949. Nevertheless, the close correspondence in the two types of information creates a strong presumption that most of the part-time and residential operators who reported any self-employment income in 1949 were reporting on their income from the farms operated.

Table 5 shows the percentage distribution of total farm-operator family incomes by source for each economic class, after adjustment for the nonreporting of farm income as described above. Farm income itself, including any other self-employment income of the operators, was 60 percent of total family income for all economic classes taken together. This source accounted for three-fourths of the total income of commercial farm families as

FARMS AND FARM PEOPLE

contrasted with only a sixth of the total for the noncommercial group. Among the commercial classes, farm income declined in relative importance from 87 percent of the total in class I to only 52 percent in class V, but increased slightly in class VI.

Wage and salary income comprised 29 percent of the total for all farm-operator families, but only 16 percent for those on commercial farms as compared with 69 percent for those on part-time and residential farms. Wage and salary income received both by operators and by other family members generally increased in relative importance from class I to class V in the commercial group, but declined again in class VI. In both non-commercial classes, wages and salaries received by the operators alone were 50 percent or more of total family income.

Other sources of income were relatively unimportant, representing 10 percent of the total for commercial farm families and 14 percent for the noncommercial group. However, they were most important of all in the case of class VI commercial farms where they accounted for a sixth of the total family income.

TABLE 5.—PERCENTAGE DISTRIBUTION OF AVERAGE FARM-OPERATOR FAMILY INCOME IN 1949 BY SOURCE, BY ECONOMIC CLASS OF FARM, FOR THE UNITED STATES

Economic class of farm	Total family income	Income of operator from farm ¹	Wages and salaries received by—		Other income of—
